Computer Graphics - Ray-Tracing II -

Philipp Slusallek

Overview

Last lecture

- Ray tracing I
 - Basic ray tracing
 - What is possible?
 - Recursive ray tracing algorithm
 - Intersection computations

Today

- History of intersection algorithms
- Advanced acceleration structures
 - Theoretical Background
 - Hierarchical Grids, kd-Trees, Octrees
 - Bounding Volume Hierarchies
- Dynamic changes to scenes
- Ray bundles

Next lecture

Realtime ray tracing

Theoretical Background

Unstructured data results in (at least) linear complexity

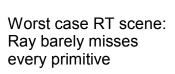

- Every primitive could be the first one intersected
- Must test each one separately
- Coherence does not help

Reduced complexity only through pre-sorted data

- Spatial sorting of primitives (indexing like for data base)
 - Allows for efficient search strategies
- Hierarchy leads to O(log n) search complexity
 - But building the hierarchy is still O(n log n)
- Trade-off between run-time and building-time
 - · In particular for dynamic scenes
- Worst case scene is still linear !!

It is a general problem in graphics

- Spatial indices for ray tracing
- Spatial indices for occlusion- and frustum-culling
- Sorting for transparency

Ray Tracing Acceleration

- Intersect ray with all objects
 - Way too expensive
- Faster intersection algorithms
 - Little effect (but efficient algorithms are still necessary)
- Less intersection computations
 - Space partitioning (often hierarchical)
 - Grid, hierarchies of grids
 - Octree
 - Binary space partition (BSP) or kd-tree
 - Bounding volume hierarchy (BVH)
 - Directional partitioning (not very useful)
 - 5D partitioning (space and direction, once a big hype)
 - Close to pre-compute visibility for all points and all directions
- Tracing of continuous bundles of rays
 - Exploits coherence of neighboring rays, amortize cost among them
 - Cone tracing, beam tracing, ...

Grid

Grid

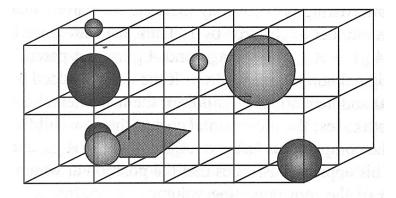

Partitioning with equal, fixed sized "voxels"

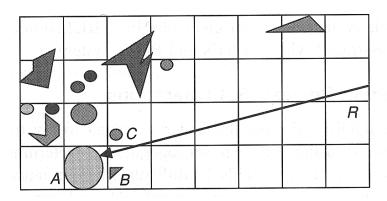

Building a grid structure

- Partition the bounding box (bb)
- Resolution: often ³√n
- Inserting objects
 - Trivial: insert into all voxels overlapping objects bounding box
 - Easily optimized

Traversal

- Iterate through all voxels in order as pierced by the ray
- Compute intersection with objects in each voxel
- Stop if intersection found in current voxel

Grid

Grid

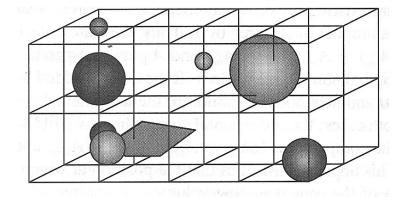

Partitioning with equal, fixed sized "voxels"

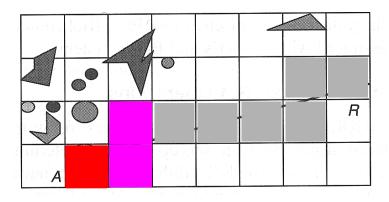

Building a grid structure

- Partition the bounding box (bb)
- Resolution: often ³√n
- Inserting objects
 - Trivial: insert into all voxels overlapping objects bounding box
 - Easily optimized

Traversal

- Iterate through all voxels in order as pierced by the ray
- Compute intersection with objects in each voxel
- Stop if intersection found in current voxel

Grid: Issues

Grid traversal

- Requires enumeration of voxel along ray
 - → 3D-DDA, modified Bresenham (later)
- Simple and hardware-friendly

Grid resolution

- Strongly scene dependent
- Cannot adapt to local density of objects
 - Problem: "Teapot in a stadium"
- Possible solution: grids within grids → hierarchical grids

Objects spanning multiple voxels

- Store only references to objects
- Use mailboxing to avoid multiple intersection computations
 - Store object in small per-ray cache (e.g. with hashing)
 - Do not intersect again if found in cache
- Original mailbox stores ray-id with each triangle
 - Simple, but likely to destroy CPU caches

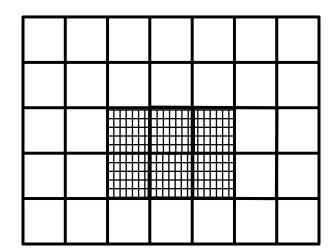

Hierarchical Grids

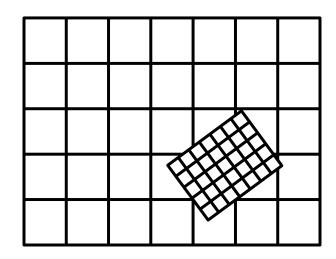

Simple building algorithm

- Coarse grid for entire scene
- Recursively create grids in high-density voxels
- Problem: What is the right resolution for each level?

Advanced algorithm

- Place cluster of objects in separate grids
- Insert these grids into parent grid
- Problem: What are good clusters?

Octree

Hierarchical space partitioning

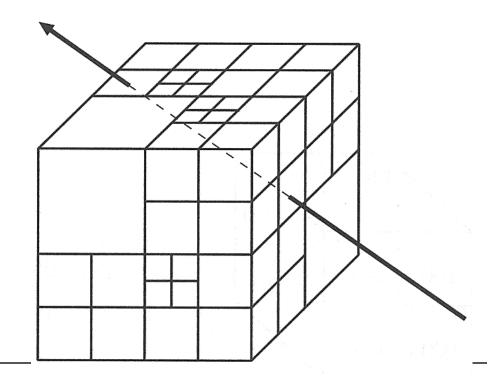

- Start with bounding box of entire scene
- Recursively subdivide voxels into 8 equal sub-voxels
- Subdivision criteria:
 - Number of remaining primitives and maximum depth
- Result in adaptive subdivision
 - Allows for large traversal steps in empty regions

Problems

- Pretty complex traversal algorithms
- Slow to refine complex regions

Traversal algorithms

- HERO, SMART, ...
- Or use kd-tree algorithm ...

Bounding Volumes (BV)

Observation

- Bound geometry with BV
- Only compute intersection if ray hits BV

Sphere

- Very fast intersection computation
- Often inefficient because too large

Axis-aligned box

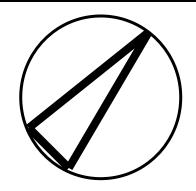

- Very simple intersection computation (min-max)
- Sometimes too large

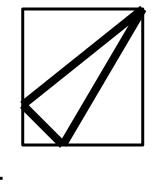

Non-axis-aligned box

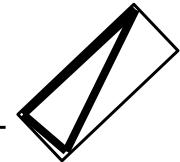

- A.k.a. "oriented bounding box (OBB)"
- Often better fit
- Fairly complex computation

Slabs

- Pairs of half spaces
- Fixed number of orientations
 - Addition of coordinates w/ negation
- Fairly fast computation

Bounding Volume Hierarchies

Idea:

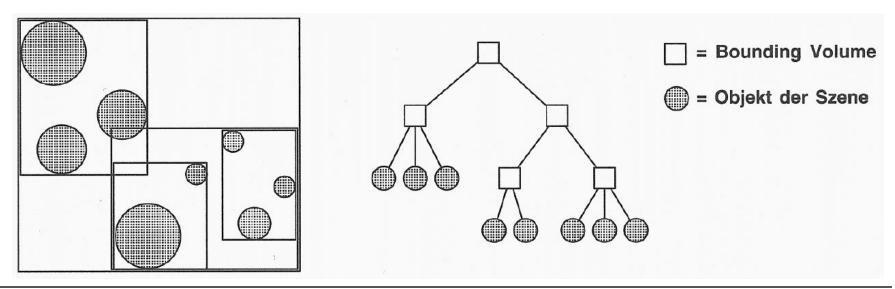

Organize bounding volumes hierarchically into new BVs

Advantages:

- Very good adaptivity
- Efficient traversal O(log N)
- Often used in ray tracing systems

Problems

– How to arrange BVs?

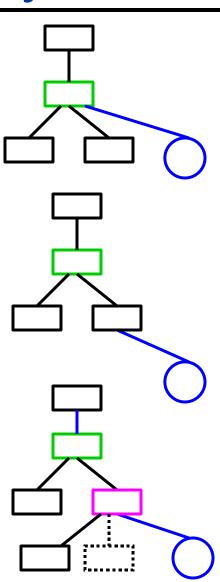

Bounding Volume Hierarchy

Possible building strategy

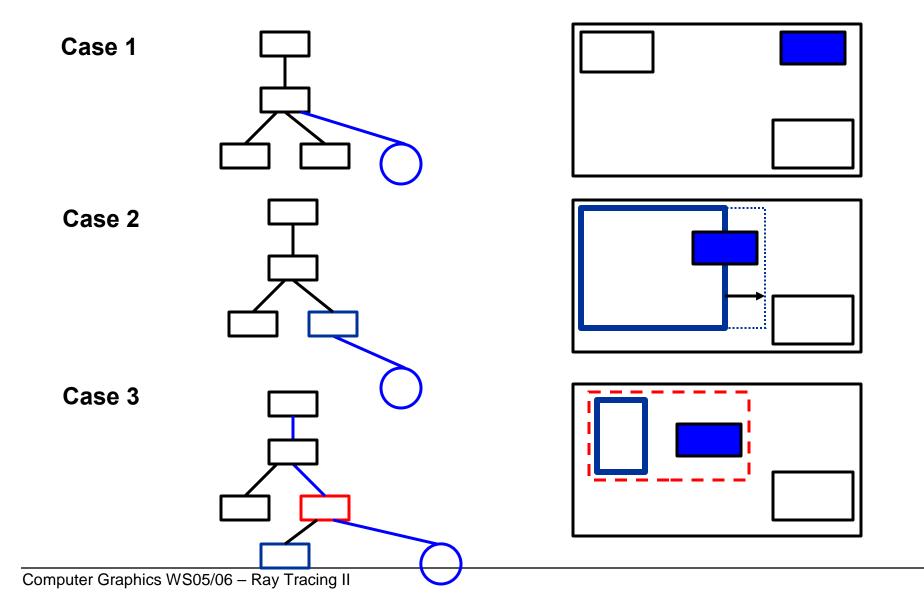

- Manual
- Given by input structure (e.g. CAD system)
- Incremental insertion (top-down)

Incremental recursive insertion

- Algorithm from Goldsmith/Salmon'87
- Cost function:
 - Surface of object / BVs
 - Cost for intersection with children
 - Local decisions only (otherwise NP-hard)
- Evaluate cost function for three cases
 - Insert as child in current BV
 - Propagate to some child and recurse
 - Create new BV as child and merge new object with other old children

Bounding Volume Hierarchy

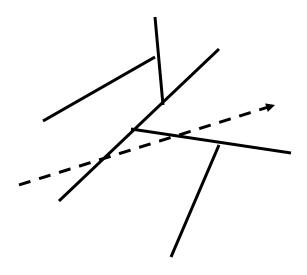

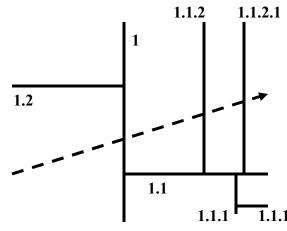

BSP- and Kd-Trees

- Recursive space partitioning with half-spaces
- Binary Space Partition (BSP):
 - Recursively split space into halves
 - Splitting with half-spaces in arbitrary position
 - Often defined by existing polygons
 - Often used for visibility in games (→ Doom)
 - Traverse binary tree from front to back

Kd-Tree

- Special case of BSP
 - Splitting with axis-aligned half-spaces
- Defined recursively through nodes with
 - Axis-flag
 - Split location (1D)
 - Child pointer(s)
- See separate slides for details

Directional Partitioning

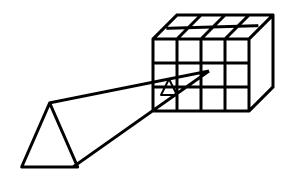

Applications

- Useful only for rays that start from a single point
 - Camera
 - Point light sources
- Preprocessing of visibility
- Requires scan conversion of geometry
 - For each object locate where it is visible
 - Expensive and linear in # of objects

Generally not used for primary rays

Variation: Light buffer

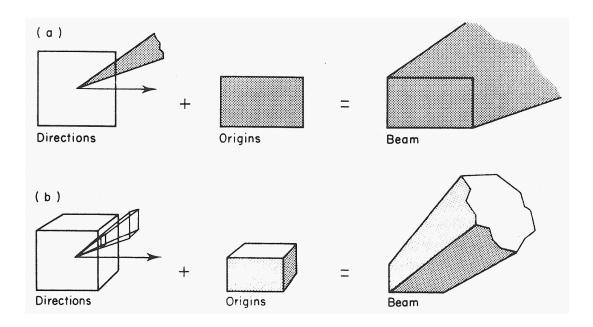

- Lazy and conservative evaluation
- Store occluder that was found in directional structure
- Test entry first for next shadow test

Ray Classification

Partitioning of space and direction [Arvo & Kirk'87]

- Roughly pre-computes visibility for the entire scene
 - What is visible from each point in each direction?
- Very costly preprocessing, cheap traversal
 - Improper trade-off between preprocessing and run-time
- Memory hungry, even with lazy evaluation
- Seldom used in practice

Dynamic Scenes

Changes to spatial indices

In interactive context

Very little research despite general usefulness

- Efficient dynamic data structures
 - From computational geometry (i.e. kinetic data structures)
 - Not realtime
- Animation with predefined motion [Glassner'88, Gröller'91, ...]
- Exclude dynamic primitives [Parker'99]
- Constant time rebuild [Reinhard'00]
- Divide and conquer [Lext'00]

Different Types of Motion

Hierarchical: Affine transformations for groups of primitives

Unstructured: Arbitrary movements of primitives

Divide & Conquer Approach

Observation

- 80/20 rule: Very often a simple approach is sufficient
- Building hierarchical index structures requires O(n logn)
 - Divide and conquer reduces complexity

Categorize primitives into independent groups/objects

- Static parts of a scene (often large parts of a scene)
- Structured motion (affine transformations)
- Anything else

Select suitable approach for each group

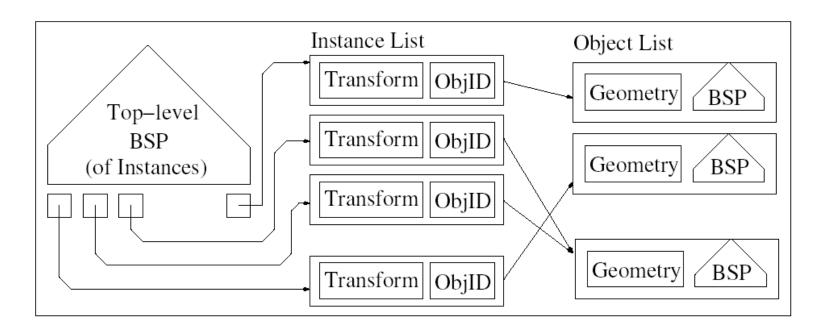

- Do nothing
- Transform rays instead of primitives
- Only update index structure for relevant groups

Divide & Conquer Approach

Two-level index structure

- Find relevant objects
- Transform ray (efficient SSE code)
- Find primitives in object
- Same kd-tree traversal algorithms in both cases

Results in some run-time overhead

Implementation

KD-tree building algorithms

- Static & structured motion
 - Build once with sophisticated and slow algorithm [Havran'01]
 - Optimize for traversal (as low as 1.5 intersection per ray)
- Unstructured Motion
 - Will be used for single or few frames
 - Balance construction and traversal time
 - Allow more primitives in deeper nodes
- Top-Level:
 - Significantly more efficient than for primitives
 - Possible splitting planes for kd-tree are already given

Implementation

Index Structure Updates

- Static: Done
- Structured Motion
 - Update transformation
 - Schedule update of top-level index
- Unstructured Motion
 - Rebuild local index and bounding box
 - Schedule top-level update, iff bounding box changed
 - Could be optimized with top-level hierarchy
 - Not yet necessary

BART Kitchen

- 110,000 triangles in 5 objects, 6 lights with shadows
- Little structured motion
- 3.8 Mrays/frame resulting in 0.9 Mrays per second and CPU
- Performance (fps)

Shading \ CPUs	2	4	8	16	32
OpenGL-like	3.2	6.4	12.8	25.6	> 26
Ray Tracing	0.47	0.94	1.88	3.77	7.55

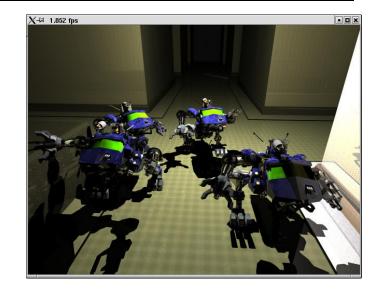

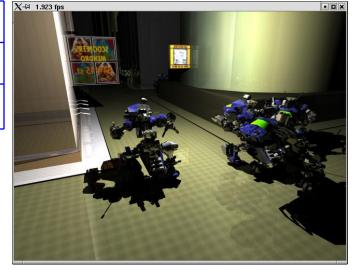

BART Robots

- 16 robots with 161 objects
- Many textures, shadows, and reflection
- Significant structured motion
- Update of top-level kd-tree: << 1ms</p>
- Performance (fps)

CPUs	2	4	8	16	32
OpenGL-like	2.8	5.55	10.8	21	> 26
Ray Tracing	0.54	1.07	2.15	4.3	8.6

Outdoor Terrain

- 661 objects, total of 10 Mtris
- Single point light source
- Accurate shadows between leaves
- Interactive translation of all trees
- Performance
 - Update for top-level kd-tree: 4ms

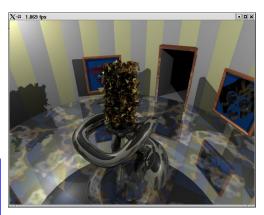

BART Museum

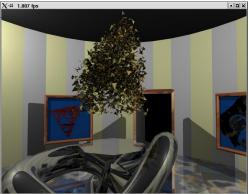

- Varying amount of unstructured motion
 - 64, 256, 1k, 4k, 16k, or 64 k triangles
- Kd-tree update

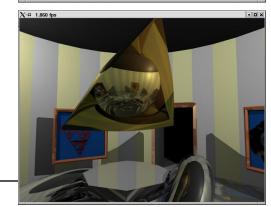

# tris	64	256	1k	4k	16k	64k
time	1ms	2ms	8ms	34ms	0.1s	> 1s
bandwidth/ client (b/f)	6.4k	25.6k	102k	409k	1.6M	6.5M

Performance (fps)

Tris \ clients	1	2	4	8	16
1k	0.6	1.2	2.4	4.8	9.3
4k	0.55	1.1	2.2	4.2	2.5
16k	0.45	0.9	1.65	0.98	0.53

Distribution Ray Tracing

- Formerly called Distributed Ray Tracing [Cook`84]
- Stochastic Sampling of

Pixel: Antialiasing

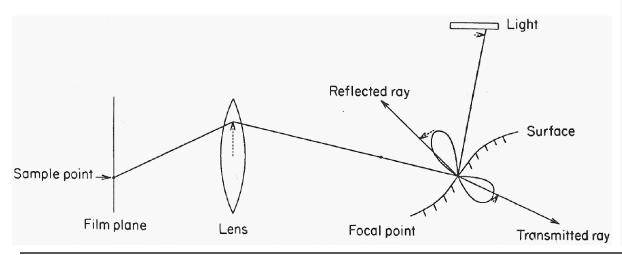

– Lens: Depth-of-field

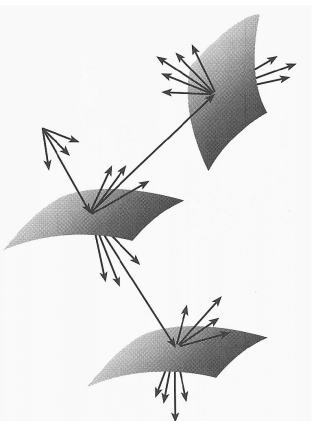

BRDF: Glossy reflections

Lights: Smooth shadows from

area light sources

– Time: Motion blur

Beam und Cone Tracing

General idea:

Trace continuous bundles of rays

Cone Tracing:

- Approximate collection of ray with cone(s)
- Subdivide into smaller cones if necessary

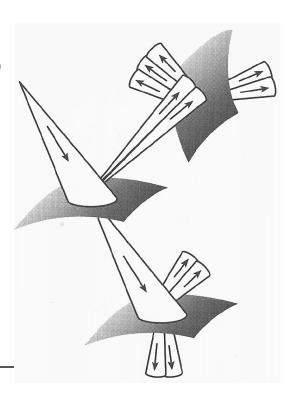

Beam Tracing:

- Exactly represent a ray bundle with pyramid
- Create new beams at intersections (polygons)

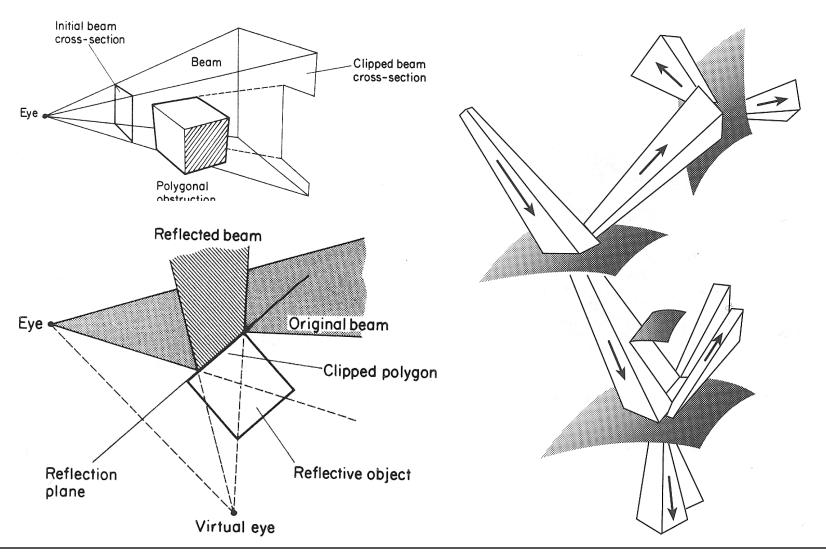

Problems:

- Clipping of beams?
- Good approximations?
- How to compute intersections?

Not really practical !!

Beam Tracing

Packet Tracing

Approach

- Combine many similar ray (e.g. primary or shadow rays)
- Trace them together in SIMD fashion
 - All rays perform the same traversal operations
 - All rays intersect the same geometry
- Exposes coherence between rays
 - All rays touch similar spatial indices
 - Loaded data can be reused (in registers & cache)
 - More computation per recursion step → better optimization
- Overhead
 - Rays will perform unnecessary operations
 - Overhead low for coherent and small set of rays (e.g. up to 4x4 rays)

Wrap Up

Acceleration Structures / Spatial Indices

- Necessary for sub-linear scalability (in scene size)
- Hierarchies achieve O(log n)
- Kd-trees offer
 - Simple building and traversal algorithms
 - Good performance for almost all scenes
- BVH are also very popular
- Dynamic changes to scenes
 - Require (partial) rebuilding of index
 - · More research required

Handling Ray Bundles

- Cone- and beam tracing are not very practical
- Packet tracing combines advantages with practical implementation
